#### 2023/2024(1) EF234302 Object Oriented Programming Lecture #6 Inheritance

мisbakhul Munir IRFAN SUBAKTI 司馬伊几 мисбакхул Мунир Ирфан Субакти

#### Inheritance: Database project example

#### • Suppose we have three classes below:

```
DB.java 🗙 🗊 LinearDB.java
                         TreeDB.java
                                                                      🕽 LinearDB.java 🗙 🚺 TreeDB.java
                                     DBTest.java
                                                              DB.java
                                                                                                DBTest.java
    1 package db;
                                                               1 package db;
    2 abstract class DB {
                                                               2 class LinearDB extends DB {
           void addSeveral(int keys[]) {
                                                                     int table[] = new int[10];
    30
                                                               3
               for (int i = 0; i < keys.length; i++) {</pre>
                                                                     int size = 0;
    4
                                                               4
    5
                    addKey(keys[i]);
                                                                     void addKey(int key) {
                                                               5⊝
    6
               }
                                                                          System.out.println("LinearDB: addKey()");
                                                               6
    7
                                                               7
                                                                      }
           boolean findOneOf(int keys[]) {
    8⊝
                                                                      boolean search(int key) {
                                                               8⊝
    9
               for (int i = 0; i < keys.length; i++) {</pre>
                                                                          boolean result = true;
                                                               9
                    if (search(keys[i])) {
   10
                                                                          System.out.println("LinearDB: searchKey()");
                                                              10
   11
                        return true;
                                                              11
                                                                          return result;
                                                                                                                       🕽 TreeDB.java 🗙 🗊 DBTest.java
                                                                                                  DB.java
                                                                                                           LinearDB.java
   12
                    }
                                                             12
                                                                      }
                                                                                                   1 package db;
   13
                                                             13 }
               }
                                                                                                   2 class TreeDB extends DB {
   14

                                                                                                   6
   18 }
                                                                                                   7⊝
                                                                                                         boolean search(int key) {
                                                                                                              boolean result = false;
                                                                                                   8
                                                                                                   9
                                                                                                              System.out.println("TreeDB: searchKey()");
                                                                                                  10
                                                                                                              return result;
                                                                                                  11
                                                                                                  12 }
                                                2023/2024(1) – Object Oriented Programming | MM Irfan
                                                                                                                                                  2
10.10.2023
                                                                      Subakti
```

## Database project example (continued)

• LinearDB has 4 operations

void addKey(int key)
boolean search(int key)
void addSeveral(int keys[])
boolean findOneOf(int keys[])

• It is as if LinearDB were defined as:

```
int table[] = new int[10];
int size = 0;
void addKey(int key)
boolean search(int key)
void addSeveral(int keys[])
boolean findOneOf(int keys[])
```

• Similarly for TreeDB

3

## Database project example (continued)

• Variables can be declared of type DB. LinearDB and TreeDB objects can be assigned to them

```
DB ldb = new LinearDB();
```

DB tdb = new TreeDB();

• There are no DB objects – we cannot say new DB() – only LinearDB and TreeDB objects

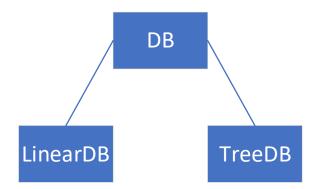

#### Database project example (continued)

• We can create a test file: DBTest as below.

```
🚺 LinearDB.java
                     TreeDB.java
                                 🚺 DBTest.java 🗙
DB.java
 1 package db;
 2 public class DBTest {
       public static void main(String[] args) {
 3⊝
            DB ldb = new LinearDB();
 4
            DB tdb = new TreeDB();
 5
            ldb.addKey(1);
 6
 7
            if (ldb.search(1)) {
                System.out.println("It's found!");
 8
 9
            } else {
                System.out.println("It's not found!");
10
11
            tdb.addKey(2);
12
13
            if (tdb.search(1)) {
                System.out.println("It's found!");
14
15
            } else {
                System.out.println("It's not found!");
16
17
18
        }
19 }
```

### Database project example: Class hierarchy

- DB is called the *superclass* or *base class*
- LinearDB and TreeDB are subclasses or derived classes
- We say LinearDB and TreeDB *inherit from* DB, because they obtain the definitions of addSeveral and findOneOf

# Inheritance: General rules from abstract superclasses

#### • Given

abstract class B { ... }
abstract C extends B { ... }

 $\bullet$  It is as if  ${\ensuremath{\mathbb C}}$  were defined as

class C { ... ... }

- That is,  ${\mathbb C}$  has all the instance variables and methods defined in  ${\mathbb B}$  in addition to its own instance variables and methods
- If we had class D extends C { ... }, D would inherit from both C and B

#### Method redefinition in subclasses

```
abstract class B { ... }
abstract C extends B { ... }
```

- A very important aspect of inheritance is that *methods can be redefined* instead of being inherited
- Real rule is: C inherits instance variables of B and instance methods of B, except those that it defines itself

#### Method redefinition

• For example, LinearDB could redefine as addSeveral as follows.
void addSeveral(int keys[]) {
 for (int i = 0; i < keys.length; i++) {
 table[size + i] = keys[i];
 }
 size += keys.length;
}</pre>

#### Inheritance from concrete classes

- It is also possible to inherit from ordinary (i.e., non-abstract, a.k.a. concrete) classes
- Works the same as inheritance from abstract classes
- The only difference is that the superclass can have its own instances
- E.g., we could have TreeDB inherits from LinearDB

#### Inheritance from concrete classes (cont'd)

```
🚺 LinearDB.java 🗙
 1 package dbconcrete;
 2 class LinearDB {
       void addKey(int key) {
 30
            System.out.println("LinearDB: addKey()");
 4
 5
       boolean search(int key) {
 6⊝
            boolean result = true;
 7
            System.out.println("LinearDB: searchKey()");
 8
            return result;
 9
10
11⊖
       void addSeveral(int keys[]) {
            for (int i = 0; i < keys.length; i++) {</pre>
12
                                                                          🚺 TreeDB.java 🗙
                                                               LinearDB.java
                addKey(keys[i]);
13
                                                                1 package dbconcrete;
14
            }
                                                                2 class TreeDB extends LinearDB {
15
                                                                       BinarySearchTree data;
                                                                3
       boolean findOneOf(int keys[]) {
16⊝
                                                                       void addKey(int key) {
                                                                4⊝
17
            for (int i = 0; i < keys.length; i++) {</pre>
                                                                           System.out.println("TreeDB: addKey()");
                                                                5
18
                if (search(keys[i])) {
                                                                6
                                                                       }
19
                    return true;
                                                                       boolean search(int key) {
                                                                7⊝
20
                                                                           boolean result = false;
                                                                8
21
                                                                           System.out.println("TreeDB: searchKey()");
                                                                9
22
            return false;
                                                                           return result;
                                                               10
23
       }
                                                               11
                                                                       }
24 }
                                                               12 }
```

#### Inheritance from concrete classes (cont'd)

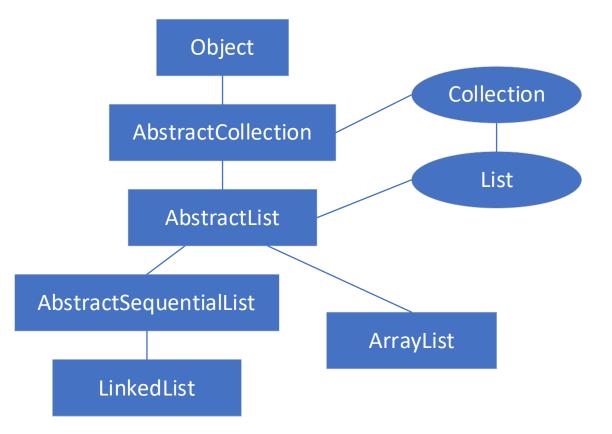

• But be careful – use of abstract classes is usually better!

```
TreeDB.java
                       🕽 DBTest.java 🗙
LinearDB.java
1 package dbconcrete;
 2 public class DBTest {
       public static void main(String[] args) {
 3⊝
            LinearDB ldb = new LinearDB();
 4
           TreeDB tdb = new TreeDB();
 5
           ldb.addKey(1);
 6
 7
           if (ldb.search(1)) {
                System.out.println("It's found!");
 8
 9
           } else {
                System.out.println("It's not found!");
10
11
12
           tdb.addKey(2);
13
           if (tdb.search(1)) {
                System.out.println("It's found!");
14
15
           } else {
                System.out.println("It's not found!");
16
17
18
19 }
```

#### Interfaces VS abstract classes

- Interfaces have only *declarations* for methods
- Abstract classes can have both *declarations as well as code* for methods
- But, the constraint is: abstract classes only support single inheritance
- We cannot inherit from multiple superclasses
- It is possible to implement several interfaces

#### Inheritance in Java API

#### Inheritance: Other example

#### • Geometric figures

Figure OpenFigure Line Curve ClosedFigure Rectangle Oval

## Inheritance: Other example (continued)

• A class hierarchy for a student information
